Outline

Background & Purpose

Data & Cleaning

Results

Models

Conclusions

Background & Purpose

Supermassive Black Holes

- Supermassive Black Holes (SMBHs) in virtually every massive galaxy
- Unknown seeding mechanisms for SMBHs (Direct Collapse, popIII stars)
- SMBHs recently have been found in high-redshift dwarf-like galaxies

Purpose: investigate the seeding and growth mechanisms of the first black holes by comparison to local dwarf galaxy AGN

Observational Methods

Methods to survey Active Galactic Nuclei (AGN)

- Optical spectroscopy.....(Biased)
- Optical, UV, IR variability(Low Contrast)
- Radio emission.....(Expensive)
- X-ray observations(Shallow and low-resolution)

eROSITA

extended ROentgen Survey with an
Imaging Telescope Array

Highest sensitivity X-ray all-sky survey
to date

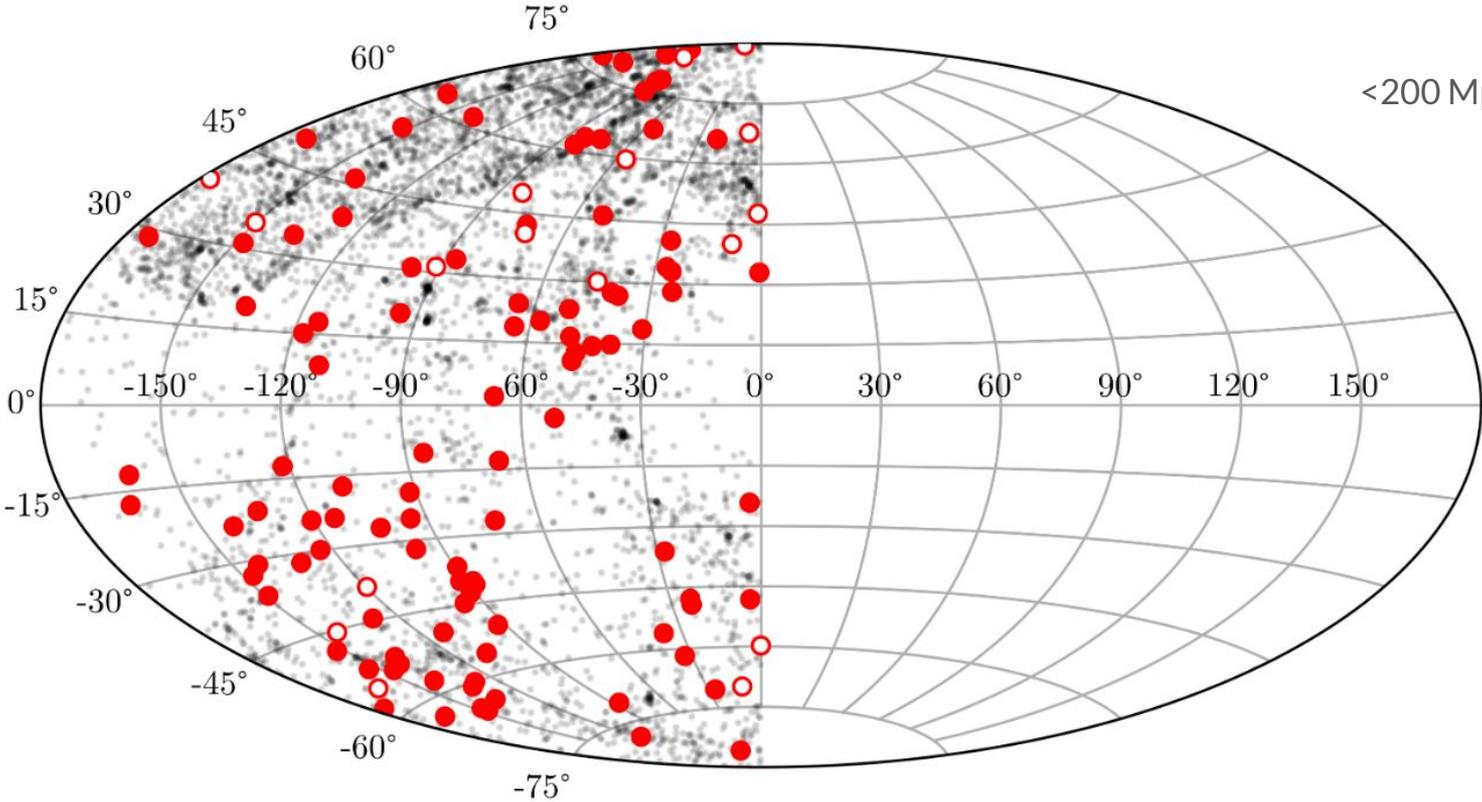

eROSITA All Sky Survey Data Release 1
(eRASS1) finds > 930,000 X-ray sources
in western half of sky

Data & Cleaning

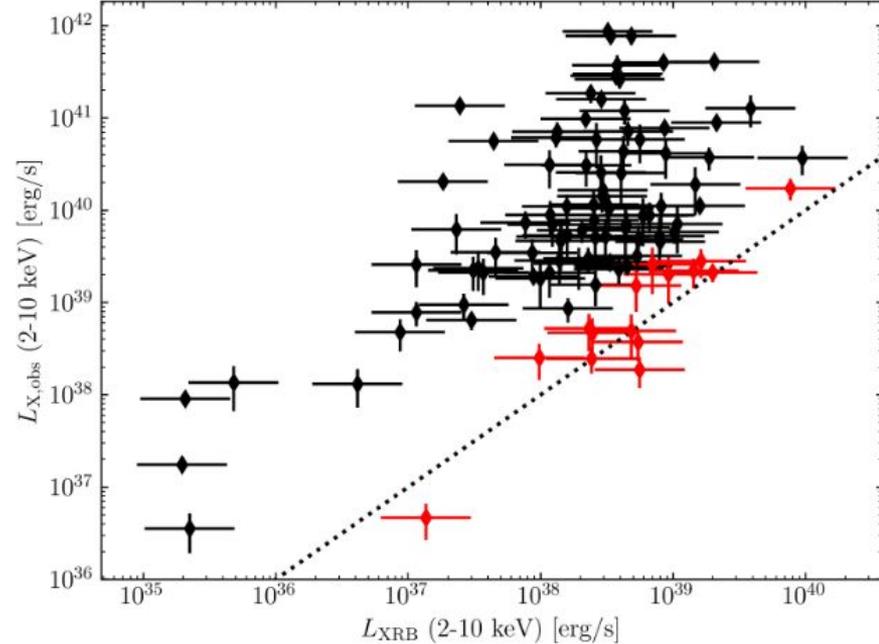

Dwarf-X-ray Matches

Unresolved X-ray Binaries

Low mass X-ray binaries (LMXBs)
emission correlates with the stellar
mass of galaxies

High mass X-ray binary (HMXB)
emission correlates with the star
forming rate (SFR) of a galaxy

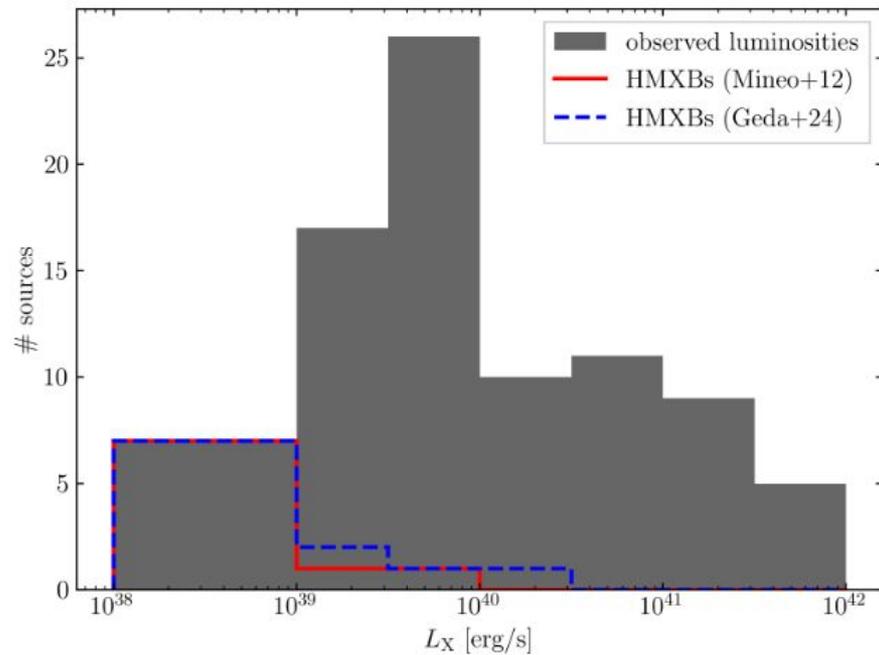

$$L_{2-10 \text{ keV}} (\text{erg/s}) = \alpha M_{\text{gal}} + \beta \text{SFR}$$

More X-ray Binaries

Removed all source with $L < 10^{39}$ erg/s

2 - 4 expected remaining HMXB contaminants

Crossmatching

XMM-Newton and Chandra telescopes

- 1 spurious detection
- 4 known ultraluminous X-ray sources (ULXs)

**74 dwarf galaxies with an
eROSITA-detected
source**

Results

X-ray Hardness Ratio

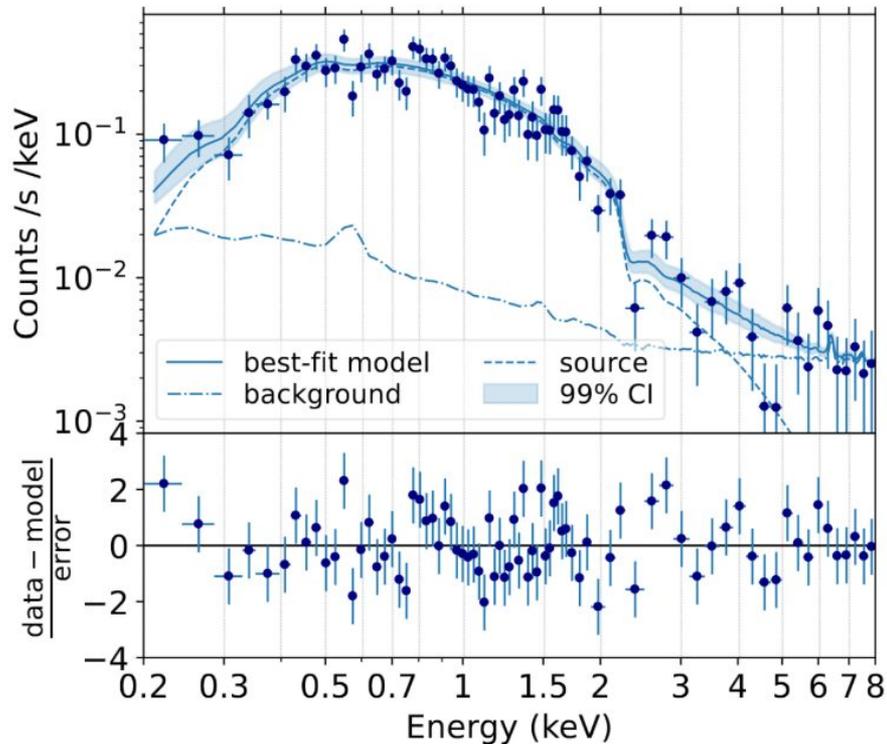

$$HR = S/M$$

S: number of counts measured in the “soft” band (0.5-1 keV)

H: number of counts measured in the “hard” band (1-2 keV)

HR = 0.98 ~ $\Gamma = 1.8$

Agrees with earlier data for AGN

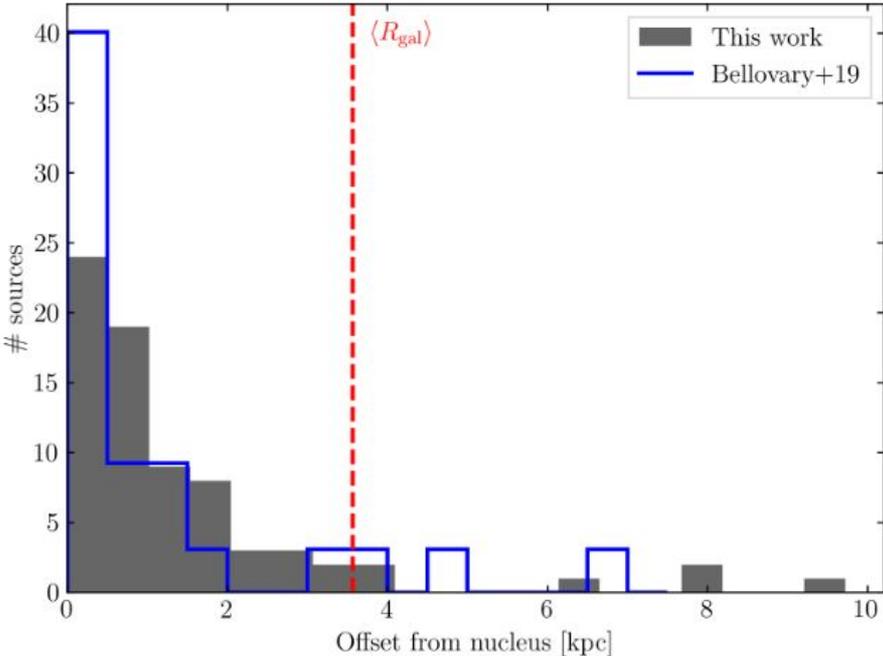

AGN Offset

Offset between galaxy centroid and X-ray source

Align with earlier work for dwarf galaxy AGN

Low spatial resolution cannot accurately place X-ray sources

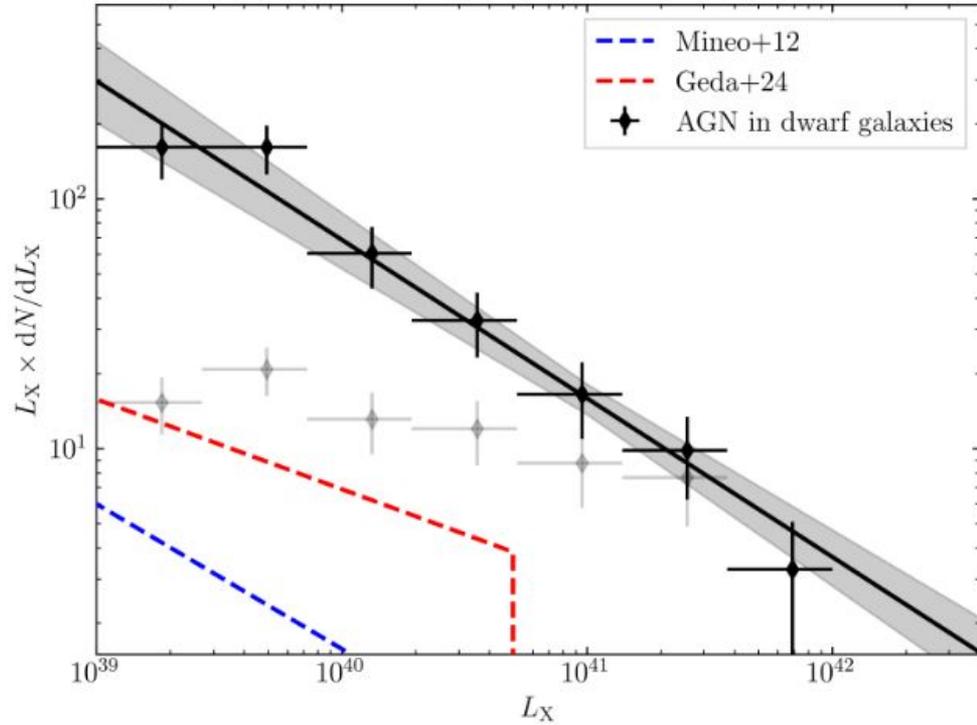

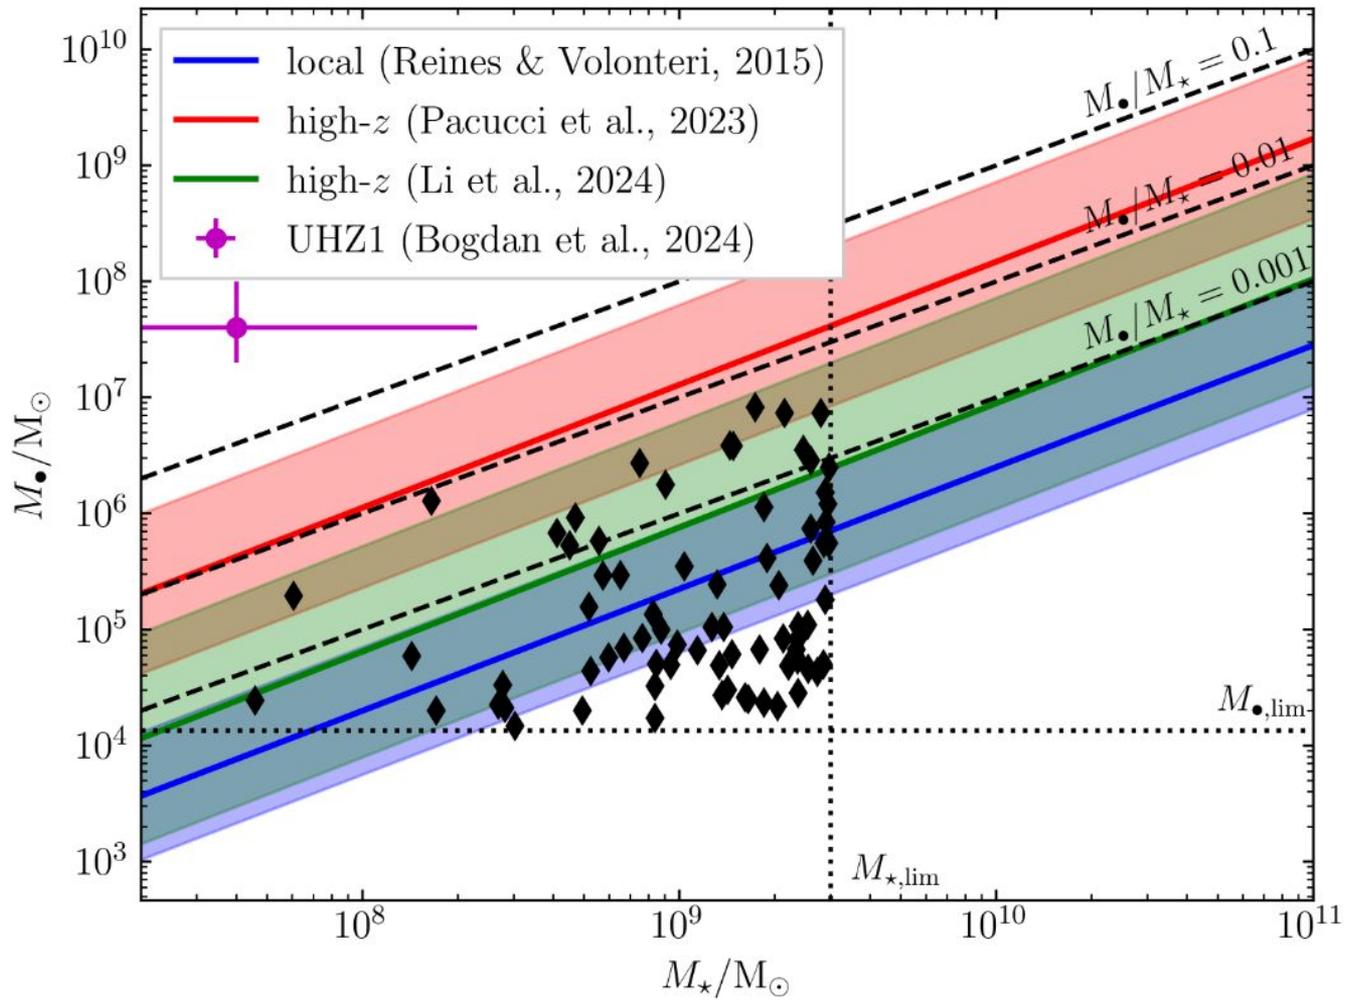

Luminosity Function

Distribution of X-ray sources per luminosity

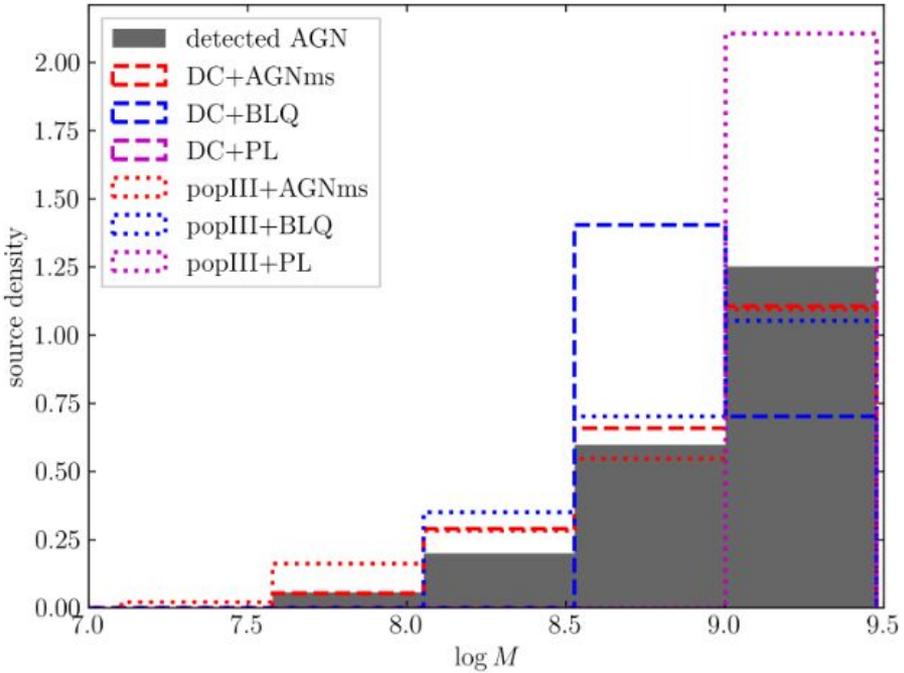

Distinct from ULX and HMXB objects

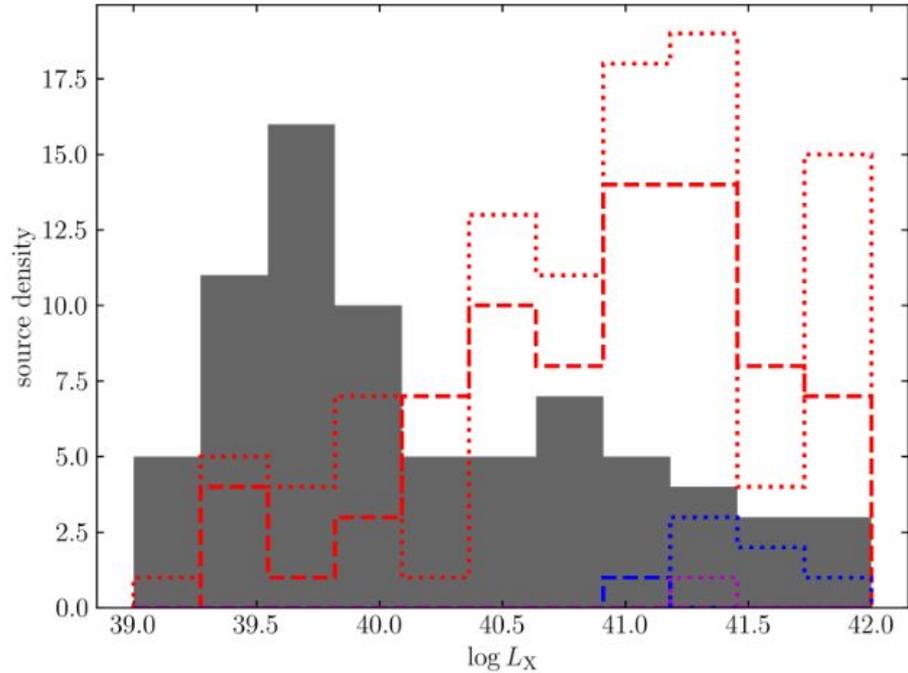

Models

AGNms: $10^{(-3)} * \text{SFR}$

Preferred accretion mode is AGNms, inconclusive for seeding mechanism
More modeling efforts to reproduce luminosity distribution

Conclusions

Conclusion

- Matched 74 likely AGN-dwarf galaxy pairs in the western half of the sky with an expected contamination of 2 - 4 non-AGN objects
- Characterized observations with the X-ray hardness ratio, off-nuclear sources, luminosity function, and black hole to galaxy mass, all of which agree with AGN expectations
- Models show that AGN accretion seems to be tied to SFR, but ultimately more modeling must be done to determine seeding mechanisms and reproduce the luminosity distribution
